Background: tidy temporal data and workflow

The tsibble package (Wang et al., 2020) introduces a unified temporal data structure, referred to as a tsibble, to represent time series and longitudinal data in a tidy format (Wickham, 2014). That said, a tsibble extends the data. frame and tibble class with temporally contextual metadata: index and key. The index declares a data column that holds time-related indices. The key identifies a collection of related series or panels observed over the index-defined period, which can comprise multiple columns. Below displays the monthly Australian retail trade turnover data (aus_retail), available in the tsibbledata package. The Month column holds year-months as index. The State together with Industry are the identifiers for these 152 series, highlighted as key. Note that the column Series ID could be an alternative option for setting up key, but State and Industry are more readable and informative. The index and key are "sticky" columns to a tsibble, forming critical pieces for fluent temporal data analysis later.

In the spirit of tidy data to the tidyverse (Wickham et al., 2019), the tidyverts suite features tsibble as the foundational data structure, in order to build a fluid and fluent pipeline for time series analysis. Besides tsibble, the feasts and fable packages fill the role of statistical analysis and forecasting in the tidyverts ecosystem. When time series analysis starts taking off, series of interest denoted by the key variables often remain unchanged over the course of analysis, from trend inspection to forecasting performance.

Figure 1 (a) gives an overview of 152 series for the retail data using an overlaid time series plot, while Figure 1 (b) presents a scatterplot, where each series is represented by a dot in the feature space (trend versus seasonal strength). The plot making of Figure 1 (b) is aided with the features() function from feasts, which summarises original data by each series down to various statistical features. This function along with other tidyverts functions is tsibble-aware, and outputs a table in a reduced form where each row corresponds to a series, thus graphically displayed as Figure 1 (b).

Figure 1 highlights not only a series with strongest seasonality, but also a need to querying interesting series on the fly. Without interactivity, one needs to first filter the interesting series out from the features table, and join back to the original tsibble in order to examine its trend in relation to others. This procedure can soon grow cumbersome if many series to be discovered. Despite that the two plots are static, they can be considered as linked views via the common key variables between two tables. This motivates enabling interactivity of tsibble and tsibble-derived objects for rapid exploratory data analysis.

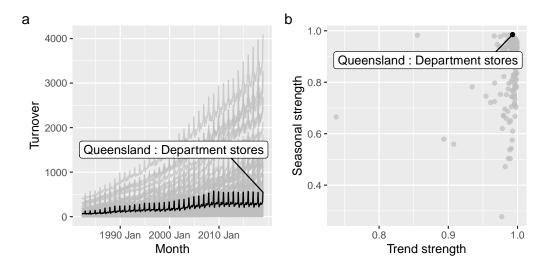

Figure 1: ToDo

Overview of interactivity

Interactivity for coordinated views via shared temporal data

The tsibbletalk package, inspired by the crosstalk package, introduces a shared tsibble data structure on top of a tsibble to allow for frictionless communication between different plots for temporal data. The as_shared_tsibble() function provides an entry point in the integrated flow, turning a tsibble to a shared instance (i.e. SharedTsibbleData subclassing of SharedData from crosstalk) that powers data transmission across multiple views. The tsibbletalk package aims to streamline interactive graphical analysis with the focus of temporal and structured linking.

As opposed to one-to-one linking, tsibbletalk defaults to categorical linking where marking one or more observations in one category will broadcast to all other observations in this category. Given time series plots, click any data point on a line, highlighting the whole line as a result. The as_shared_tsibble() uses tsibble's key variables to achieve these types of linking, and the spec argument takes one step further in constructing hybrid linking, such as hierarchical and categorical linking. For example, each series in the aus_retail data corresponds to all possible combinations of the State and Industry variables. They are intrinsically crossed with each other. If one variable is nested within another, this lends itself to a hierarchical structure, like geographical hierarchy. Such collection of inter-related time series are referred to as hierarchical and grouped time series in the literature (Hyndman and Athanasopoulos, 2017).

To incorporate structured specifications in the key, a symbolic formula can be passed to the spec argument. Adopting Wilkinson notations for factorial models (Wilkinson and Rogers, 1973), the spec follows the / and * operators tradition to declare nesting and crossing variables respectively. The spec for the aus_retail data is therefore specified as State * Industry or Industry * State, which is the default for the presence of multiple key variables. If there is a hierarchy in the data, using / is required to indicate the parent-child relation, as strictly one direction parent/child.

The tourism_monthly dataset packaged in tsibbletalk, contains monthly domestic overnight trips across Australia, to give an illustrator of nesting and crossing. The key is comprised of three identifying variables: State, Region, and Purpose (of trip), in particular State nesting of Region, together crossed with Purpose. This specification can be translated as follows:

```
library(tsibbletalk)
tourism_shared <- tourism_monthly %>%
  as_shared_tsibble(spec = (State / Region) * Purpose)
```

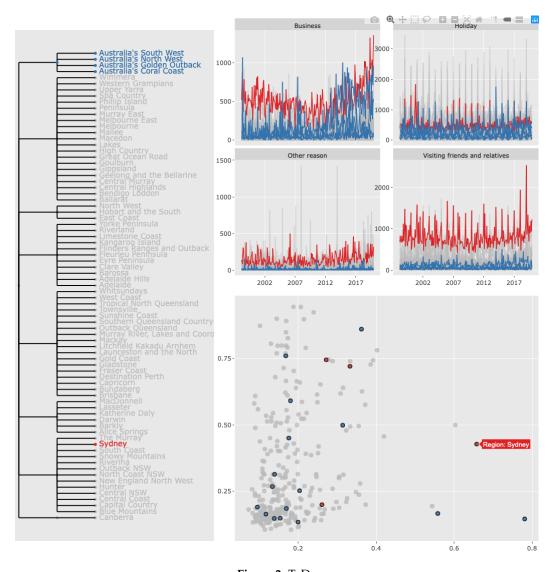

Figure 2: ToDo

This dataset contains a three-level hierarchy: the root node is implicitly Australia, and geographically disaggregated to states and lower-level tourism regions. A new handy function plotly_key_tree() has been implemented to address the need of hierarchical discovery arising from the data. It interprets hierarchies in the shared tsibble's spec as a tree view, built with plotly. The following code line produces the linked tree diagram and fills the left panel of Figure 2. The visual of tree hierarchy untangles a group of related series and snapshots the data organisation from a bird's eye view.

```
p_l <- plotly_key_tree(tourism_shared, height = 1100, width = 800)</pre>
```

The tree plot provides backbones of the data, and much flesh yet to be attached. Small multiples of time series lines are composed and placed at the top right of Figure 2 to unpack the temporal trend across regions by purposes of trips. The shared tsibble data can be directly piped into ggplot2 code.

```
p_tr <- tourism_shared %>%
  ggplot(aes(x = Month, y = Trips)) +
  geom_line(aes(group = Region), alpha = .5, size = .4) +
  facet_wrap(~ Purpose, scales = "free_y") +
  scale_x_yearmonth(date_breaks = "5 years", date_labels = "%Y")
```

To tease apart these overlaid time series, they are funnelled through the features() S3 method to extract some key characteristics, including the measurements of trend and seasonality. A scatterplot is populated from these statistics for each series.

```
tourism_feat <- tourism_shared %>%
  features(Trips, feat_stl)
p_br <- tourism_feat %>%
  ggplot(aes(x = trend_strength, y = seasonal_strength_year)) +
  geom_point(aes(group = Region), alpha = .8, size = 2)
```

Lastly, three graphics are composed as an ensemble of coordinated views for multi-facetted exploration, shown as Figure 2 (the interactive realisation of Figure 1). Routine functions bring about new interaction with temporal data on the client side.

```
subplot(p_l,
   subplot(
     ggplotly(p_tr, tooltip = "Region", width = 1100),
     ggplotly(p_br, tooltip = "Region", width = 1100),
     nrows = 2),
   widths = c(.4, .6)) %>%
   highlight(dynamic = TRUE)
```

Since all plots are stemmed from one shared tsibble data source, they are self-linking views. Nodes, lines, and points are hoverable and clickable. Given the spec, clicking either one element in any plot highlights all points that match the Region category, briefly "categorical linking". In Figure 2, when hovering and selecting the circle associated with "Sydney" in the scatter plot, all data records with shared values of "Sydney" listen and react to this interaction via self updating in red. In order for comparison with other regions or states, press the "Shift" key to enable persistent selection, and simultaneously select the parent node on the tree, saying "Western Australia", to include all the children by switching to the blue colour. The domestic tourism sees Sydney as one of the most popular destinations in realm of business and friends visiting over years. Despite of relatively weaker performance in Western Australia, Australia's North West region sees the strongest upward trend, bypassing Sydney in some years.

In summary, shared tsibble data nicely bridges between the <code>crosstalk</code> and <code>tidyverts</code> ecosystems. The <code>as_shared_tsibble()</code> provides a symbolic user interface for effortless construction of a hybrid of hierarchical and categorical linkings. And the <code>plotly_key_tree()</code> in turn decodes the specification to plot a tree for data overview and navigation, accompanied with more detailed plots.

Slicing and dicing time

The other critical aspect of a tsibble is "index", that provides foundational temporal context. A common tool in time series analytical toolkit is seasonal plots that lay time series not on the whole time scale, but on an origin-less relative time unit, for example gg_season() in the {feasts} package. It helps to examine and emphasise periodic/aperiodic patterns, comparing to time series plots that primarily focus on trends. Standard seasonal plots break the overall time into two components: seasonal periods

on the x-axis, and grouped by their corresponding lower-resolution time. For example, monthly data can be decomposed into months separated by years, and hourly data into hours grouped by days. Data collected at lower-level resolutions often exhibits more than one seasonal patterns. To discover typical seasonal or non-typical profiles, it is helpful to quickly browse through many possible periods. Interactivity ought to be enabled.

The {tsibbletalk} package provides a pair of UI and server functions, as a shiny module, to help with finding interesting time slices in a shiny application. The pair, decoupled to tsibbleDiceUI() and tsibbleDiceServer(), presents a clean interface and forms a resusable piece. Like all shiny modules, users should supply a unique session id. The UI function tsibbleDiceUI() shows a slider that controls the number of periods, and a plot specified by users. The server function tsibbleDiceServer() is the workhorse, transforming data and updating the plot. It expects a ggplot (converted to plotly via ggplotly()) or plotly object. This plot can be line charts, or other graphical elements (such as boxplots). But it assumes that tsibble's time index is plotted on the x-axis. The other mandatory argument is to specify the number of seasonal periods that requires shifting.

(Data flows) Transformed data generally requires redrawing the plot, and worsen the performance of shiny. The underlying tsibble data is called back and transformed in R. Using the plotly.js react method, only transformed data is sent to the server side, while keeping the rest configuration unchanged (e.g. layout and graphical elements). It is performant, and users will not experience notable delay in response to the change in the slider input. Dissect time index, and propagate transformed data to shiny server.

Conclusions and discussions
